# Eobd Facile Serial Code

java programing As noted in an earlier article the net has already been given the how-to-install-and-use-an-internet-server tagline: How to Install and Use an Internet Server with Windows Server 2003 IIS 7 Tutorial . In this second article I will cover the steps on installing and using an internet server with Windows XP and IIS 6.0. 1. Register and Install the IIS 6.0 Server Open a web browser and type in to start the installation. Accept the license agreement and agree to the Windows Installer EULA, if required. A small installer window appears and install the IIS 6.0 server. Wait for the installation to complete and then restart the computer. 2. Register and Install the IIS 6.0 Client A small installer window appears and install the IIS 6.0 client. Wait for the installation to complete and then restart the computer. 3. Create a folder for IIS to reside in and change the IIS 6.0 Application Pool's Default Application Pool to DefaultAppPool Right-click on the Computer icon on the desktop and select Properties. Select the Directory tab and then click the Change button. A "Select a folder for your IIS settings" window appears. Browse to and then select the directory you wish to use for IIS, for example, C:\Program Files\IIS 6.0. Click the Ok button. Select the Administrative tab and then select IIS 6.0. On the left, the Applications Pools section has one listed called DefaultAppPool. The right side of the window has an option to Add Application Pool. In the right hand panel, the Application Pool name is set to DefaultAppPool. Click the Edit button to make the changes. 4. Create a New Site Right-click on the IIS 6.0 directory and select Create Website. In the newly created website, enter the name of your site (for example MySite). Set the Website Directory to the location you wish to store your site and then select Create 82157476af
